

# Demand Curve

# Individual demand curves

A demand function represents how the quantity demanded of a good depends on different factors, such as price, income and preferences.

# Individual demand curves

A demand function represents how the quantity demanded of a good depends on different factors, such as price, income and preferences. The quantity demanded of good  $x$  is given by

$$D_x = d_x(P_x, P_y, I, \text{Preferences}, \text{other factors})$$

The diagram shows the demand function equation  $D_x = d_x(P_x, P_y, I, \text{Preferences}, \text{other factors})$  with several annotations. A red arrow points to the dependent variable  $D_x$ , which is enclosed in a pink oval. The function  $d_x$  is enclosed in a yellow oval. The arguments  $P_x$  and  $P_y$  are grouped by a bracket underneath, with an arrow pointing to it from below. The argument  $I$  is circled, with an arrow pointing to it from below. The arguments  $\text{Preferences}$  and  $\text{other factors}$  are grouped by a bracket underneath, with an arrow pointing to it from below. The entire term  $\text{other factors}$  is enclosed in a yellow oval.

# Consumer optimum

Where the IC and budget line "meet".

## Changes in consumer's optimum

Consumer demand for a good depends on - (1) their Indifference curve (preferences), and (2) their budget line (prices and incomes).

# Changes in consumer's optimum

Consumer demand for a good depends on - (1) their Indifference curve (preferences), and (2) their budget line (prices and incomes).

In other words, every change to the system should be evaluated from the following perspective – does it affect the indifference curve or the budget line, and how will that affect the eventually demanded bundle?

What happens to the demand of a good when its own price decreases? **Good X**  $P_x \downarrow$  demand of x ?  
Pivot.

## Price $\downarrow \rightarrow$ budget line pivots

If  $P_x \downarrow$ , then the budget line pivots to the right.

1. Since  $P_x$  falls, the maximum amount of good  $x$  that can be bought increases. This shifts the  $x$ -intercept to the right.

2. The slope of the budget line is given by  $-\frac{P_x}{P_y}$ . A decrease in  $P_x$  leads to a fall in the absolute value of the slope, thus leading to flatter budget line. But note that since  $P_y$  is held constant, the  $y$ -intercept is unchanged.

Price ↓

New optimal consumption bundle

The new optimal consumption bundle ( $X^{**}$ ,  $Y^{**}$ ) is on the **new** budget line.

# Demand function

Now examining income changes...

$$D_x = d_x(P_x, P_y, I, \text{Preferences, other factors})$$

# What happens to demand when only income changes?

Case of an increase in income.

A  $\rightarrow$  initial optimum  
(choice)

B  $\rightarrow$  new optimum  
(more of  $x$  and  
more of  $y$ )

# What happens to demand when only income changes?

Suppose income increases keeping all other things constant (*ceteris paribus* assumption), then what happens to demand?

Assuming that initially, the consumer's demand looks like:

# What happens to demand when only income changes?

Now let the consumer's income increase from  $I_1$  to  $I_2$ , then the consumer's budget line shifts parallelly to the right.

# What happens to demand when incomes change?

A **normal good** is one where the demand for the good goes up as incomes increase.

Can demand ever go down when income increases?

$I \uparrow$        $x \uparrow$        $y \uparrow$       No!  
Inferior goods

## Can demand ever go down when income increases?

An **inferior good** is one whose demand goes down as incomes go up. Example - flip phones.

# Can demand ever go down when income increases?

An **inferior good** is one whose demand goes down as incomes go up. Example - flip phones.

Let there be two goods -  $z$  and  $y$ , where good  $z$  is an inferior good. Now if incomes go up from  $I_1$  to  $I_2$ , then

# What is the demand curve, and how do we derive it?

Only using the things we have learnt in this course...

SCRATCH

Left  $P_1 \rightarrow P_2 \rightarrow P_3$

# What is the demand curve, and how do we derive it?

Only using the things we have learnt in this course...

# Demand curve

Deriving a demand curve from scratch.

Suppose, initially the price of good  $x$  is  $P'_x$ , then,

# Demand curve

Let price of good  $x$  decrease from  $P'_x$  to  $P''_x$ , then,

# Demand curve

Let price of good  $x$  decrease further from  $P''_x$  to  $P'''_x$ , then,

# Demand curve

The individual's demand curve is given by the yellow line.

Are there exceptions to the "rule"?

Can demand for a good go down when price decreases?

Yes.

Giffen goods  
does not obey law of demand

$P_x \uparrow$   $X_T ?$

# Are there exceptions to the "rule"?

Can demand for a good go down when price decreases?

# What happens to demand curves when incomes increase?

Try Yourself - solution provided below.

Income  $\uparrow$   
Normal

Inferior

# What happens to demand curves when incomes increase?

Try Yourself - solution provided below.

When incomes go up, the individual is *richer* and their demand for the good increases (if it is a normal good), and the curve shifts out to the right.

Price of X ↓

Decomposing the total effect into two parts

Split-up

Intermediate  
step.

## Price of X ↓

Decomposing the total effect into two parts

This change in consumption from  $(X^*, Y^*)$  to  $(X^{**}, Y^{**})$  can be decomposed into two different effects:

1. Substitution effect
2. Income effect

## Substitution effect

New prices, Old Utility

$P_x \downarrow$ , which means  $x$  has become relatively cheaper than  $y$ , making the consumer substitute away from  $y$  towards  $x$ .

## Substitution effect

New prices, Old Utility

$P_x \downarrow$ , which means  $x$  has become relatively cheaper than  $y$ , making the consumer substitute away from  $y$  towards  $x$ .

$A \rightarrow B = \text{Total effect}$   
 $A \rightarrow C : \text{S.E.}$        $C \rightarrow B : \text{I.E.}$

## Income effect

New prices, New Utility

$P_x \downarrow$ , which means that the individual now feels like they have extra income (*richer*), which means that they buy more of both  $x$  and  $y$ .
